

Introduction to Node.js - Lecture Notes by Milind Mishra

* for a very long time only runtime that existed was "Browser".

Until 2009, Ryan Dahl (creator of Node.js) made a new runtime by taking out the Chrome's V8 - Engine & made it into Node.

Node.js is X NOT A FRAMEWORK, instead it's a RUNTIME

↳ Extracted features of JS ! (Core JS) out of browser. directly run it in our shell, enabled more! ref.

Since, Node.js was able to be run in the shell it could access OS-specific features & APIs like file system, os modules etc...

Nodejs → JS in shell (terminal)

→ RUNTIME!, but different from Browser runtime, it eliminated all irrelevant Browser based APIs like DOM etc... & externally provided a new set of API's that were helpful for backend development. Relevant CRUD operations, more os-specific architecture features

Essentially when we run a Nodejs based file we run it using cmd
node <filename>.js → runs on system, loads js in RAM & does everything.. @ NODE environment

NOTE:

there are more ^{<Runtime>} environments as well, like deno.js, bun etc..

↓
OS - features

FEATURES OF NODE JS

- * open-source, created by Ryan Dahl released @ 2009.
- * Brings raw JS features into our terminal so we can interact with OS-based features.

Difference b/w Runtime & application Framework:

Runtime

environment

provides a set of resources for a particular program or process to run.

Framework

ex: How you cook food:

✓ buy groceries, bring home & cook
✗ You don't go to farm grow food & all
already done by farmer (provide resources).

{ set of industry practices already provided by a framework for us to focus on solving problems }

like some come w/ built-in Auth ... etc.

* Resources: RAM, Disk, GPU etc.. compute power (CPU) ...

* features: when we install OS, OS specifies a list of features to interact w/ these resources & solve some issues provide GUI, UI etc..
Read / write, process running in RAM ... etc.

Things we can do with **Node.js**, difference b/w Browser based APIs & Node.js APIs.

Since node runs on our terminal we can,

- Make server-side applications.

- Desktop appⁿ

- IoT application

Raspberry → Linux → Node → install → access lots of features & solve problems in IoT.
or microcontrollers ...

- access to file system

- Processes & runtime variables.

- Timer

* Even frontend specific libraries & frameworks depend on Node for their huge use-case like React.js, Angular, Vue.js, Solid, Ember.js, etc. (many ...)

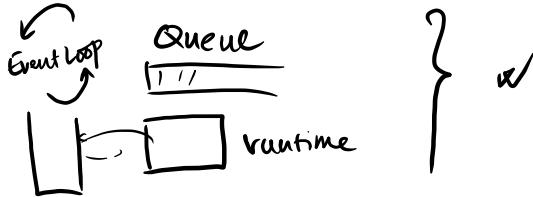

Internal features of Node.js ✓

I/O - input / output (expenses)

Blocking

Non-blocking I/O (async.js)

thread - gets blocked.

Node.js → install LTS.
↳ version manage
↓
(nvm)

“Libuv” ?? usecase

- .. Node.js internally uses it
- .. assigns threads

Node.js architecture / mechanism :-

Non-blocking

Event Loop

Macrotask queue | _____|

Microtask queue

(A)

Runtimes

Event Demultiplexer

app^h event registers

parks corresponding queues.
after execution

[operation / handler]

for, callback operation

maps corresponding queues to respective handlers.

Multiplexing

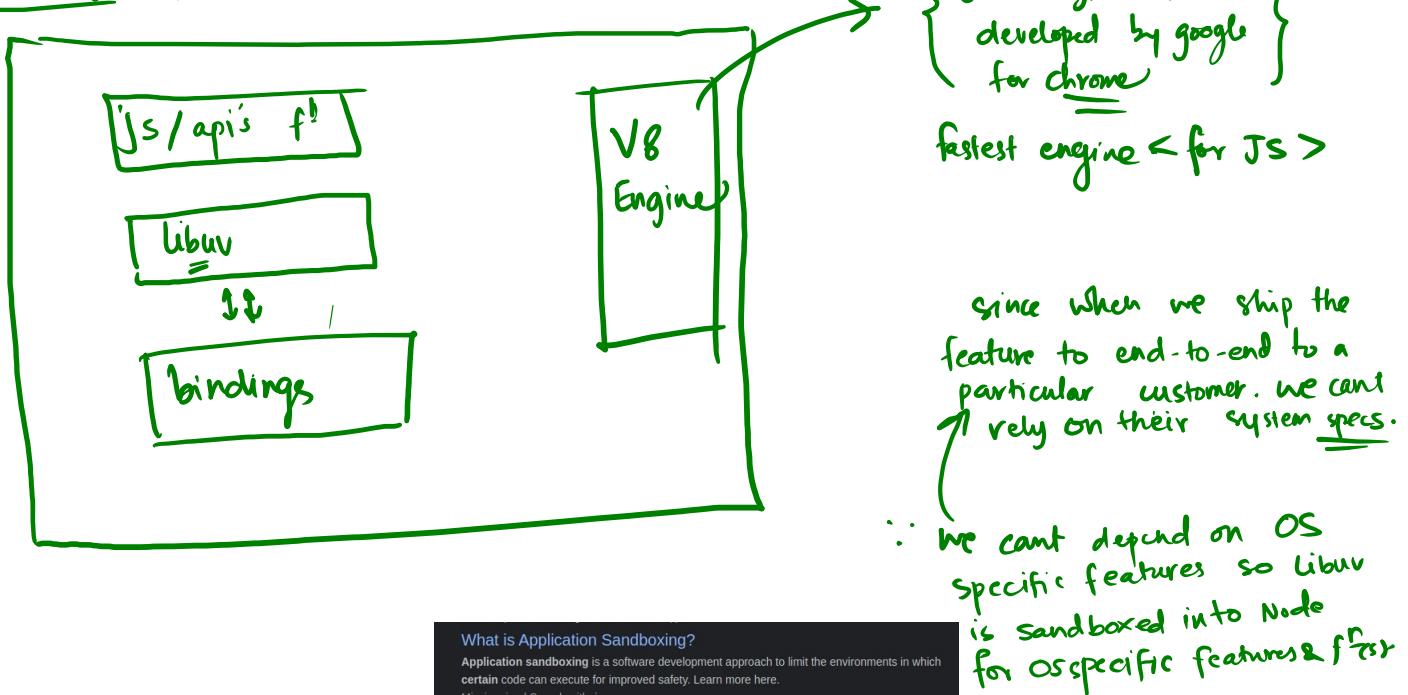

MISO

SIMO
or

Demultiplexing

(few input multiple output)

Node.js Architecture Introduction :-

since when we ship the feature to end-to-end to a particular customer, we can't rely on their system specs.

∴ we can't depend on OS specific features so libuv is sandboxed into Node for OS specific features & firs

ex: "fs" in Linux is blocking I/O, but Node is non-blocking I/O ... etc.

library → "libuv" prepared by Node.js core team

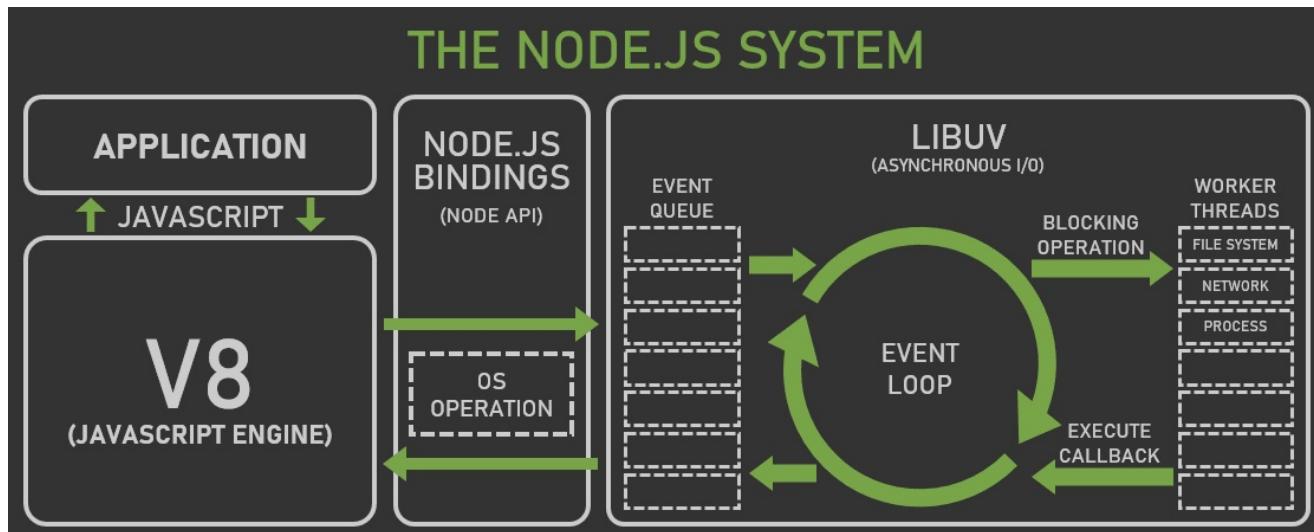

written in C++ makes Node compatible w/ all O.S.

very exciting features into Node ✓

libuv - I/O bindings for Node, low level I/O based implementations for Node
(consistent APIs) ✓

bindings - special program that helps Node to access the "libuv".

Node.js works on "Event Driven Architecture".

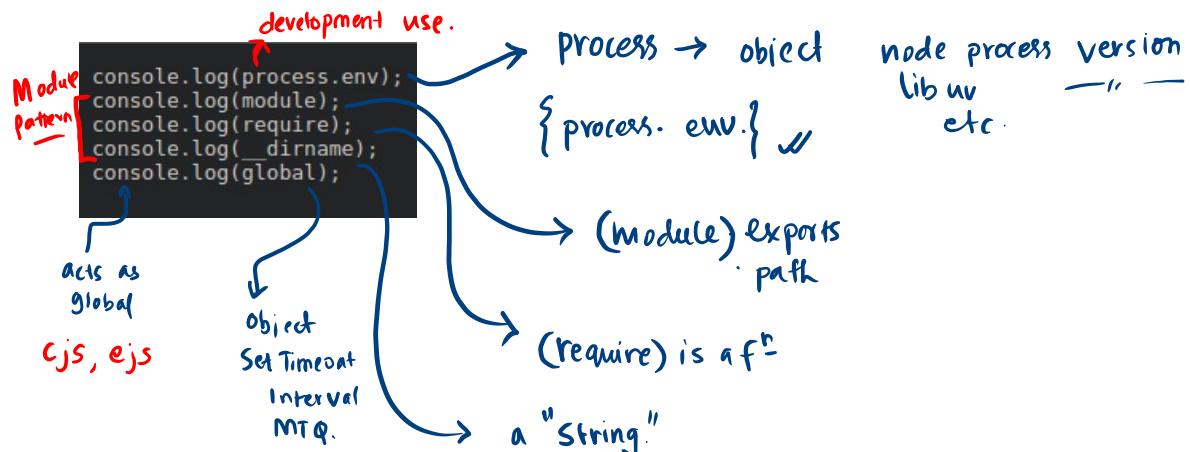

- Globals ✓
- Module pattern → Create our own, use 3rd party & make project... ✓
- Streams ✓

Globals in Node.js

- ↳ Global variables available everywhere in node
- process { helps access process variables, current process, env.var }
- __dirname { access current dir. }
- require → (other module) or DOM.
- global → { just like window object in browser runtime }
- module → access module pattern. ✓ of node.js

* there are cases where you care when we can't access specific globals
ex: can't access `__dirname` everywhere / everytime during certain config".

* NOTE: never update a global var → might just be a catastrophe for others working in the project.

** Changing globals hampers other's execution of code as there's code dependencies on global objects/vars etc..

* NOTE: different runtimes can implement similar feature of JS differently.
like `setInterval` in Node spits out an object & in browser it spits a number.

✓ All you can do is just read through description of these API's. ✓

(Wierd?)
No!

In (REPL) if nothing is returned @ current line it returns "undefined"
(browser) or (Node)

Because they're just different RUNTIMES

```
Terminal
09:20:58 milind-lab@milind-labpc ~ > node
Welcome to Node.js v16.13.0.
Type ".help" for more information.
> console.log(process);
process {
  version: 'v16.13.0',
  versions: {
    node: '16.13.0',
    v8: '9.4.146.19-node.13',
    uv: '1.42.0',
    zlib: '1.2.11',
    brotli: '1.0.9',
    ares: '1.17.2',
    modules: '93',
    nghttp2: '1.45.1',
    napi: '8',
    llhttp: '6.0.4',
    openssl: '1.1.1l+quic',

  }
}
undefined
>

```

NOTE:

Like discussed, the runtimes are different & acts differently and hence "this." acts differently in browser vs Node. as well

Table of values of `this` keyword in different environments and different modes

- Node Environment

<code>this</code> Context	Non Strict Mode	Strict Mode
Global Context	Empty Object ()	Empty Object {}
Function Context	Global Object ()	<code>undefined</code>
Object Context	Object itself	Object itself
Object Function Function Context	Global Object	<code>undefined</code>

- Browser Environment

<code>this</code> Context	Non Strict Mode	Strict Mode
Global Context	Window Object	Window Object
Function Context	Window Object	<code>undefined</code>
Object Context	Object itself	Object itself
Object Function Function Context	Window Object	<code>undefined</code>

- The thing with react is it by default runs on strict mode.
- Arrow functions are not bound to the `this` keyword, we can use `bind` method to bind the `this` keyword.
- Normally, we can use variables simply by using the name of the variable but in arrow functions, we cannot access the variables.
- `this` in context of arrow functions is empty object.
